Declaration of Authorship

I, Usman Qureshi, declare that this thesis titled, 'Machine Learning based Analysis of Greenhouse Gases in Middle East' and the work presented in it is my own. I confirm that this work submitted for assessment is my own and is expressed in my own words. Any uses made within it of the works of other authors in any form (e.g., ideas, equations, figures, text, tables, programs) are properly acknowledged at any point of their use. A list of the references employed is included.

Abstract

Greenhouse gases emission in the world is increasing in a continuous way and has environmental and health effects with humans being the main factor contributing to the disruption of the scale of the Greenhouse gases. This project uses the Middle Eastern Greenhouse Gases' dataset to find out which machine learning algorithm provides the largest accuracy and find out which sector of the countries is responsible for such high emissions. There were several types of research conducted on different datasets of the world in different countries in order to get a deeper understanding of the Dataset. But no such research was conducted on the Middle Eastern dataset.

This project experiments with multiple Machine Learning algorithms for analyzing the middle eastern GHG data from the year 1990-2016. Three machine learning algorithms are used namely Linear Regression, Support Vector Machines, and Decision Tree for evaluating the best algorithm through their accuracy. This paper looks at different research papers which tests algorithms in order to find the best machine learning algorithm for the project.

Acknowledgements

First and foremost, I would to thank my supervisor **Smitha S. Kumar** for helping me decide this topic and continuing to support me throughout the dissertation. I would also like to thank **Andrew Ireland**, my second reader, for giving me valuable feedback for the first deliverable.

Chapter 1

Introduction

Data mining of Greenhouse Gases(GHG) is really important for the society as it helps to get a better understanding of the environment and to find solution for the problems caused by it, since, for decades, there has been a sharp increase in Greenhouse Gases(GHG) throughout the world and with it, the global average temperatures ha increased by more than 1° since pre-industrial times(Ritchie and Roser, 2017). Energy consumption, environmental degradation, and climate change are all closely related. To tackle such problems, this dissertation first understands the concentration of greenhouse gases in the different regions of the world and finds out which sector contributes most to the increase in GHG's.

For this project we are going to be implementing Data Mining and Machine Learning algorithms on the Middle Eastern dataset. For this dissertation, Middle Eastern dataset was chosen because there hasn't been much research conducted on this particular dataset.

1.1 Aim

The aim of the project is to use the Middle Eastern GHG's dataset to find out which machine learning algorithm provides the largest accuracy and create an interactive web application to show the sectors of the countries contributing to the high emission of Greenhouse Gases.

1.2 Objective

The main objective of this dissertation is to get information from the dataset from the year 1990 till 2016 and accomplish the following tasks:

- Data set analysis and preprocessing
- Run multiple Machine Learning algorithms to find out which algorithm gives the best result.
- Find out which Sector of the Country is responsible for its high emission.
- Design a web application to visualize the data.

1.3 Document Overview

The document is organized in such a way that the flow of the document is maintained, with that the **Literature Review** is first covering the background i.e., research into the data mining and machine learning algorithms on GHG datasets. Next, **Requirements Analysis**, which is going to cover requirements and outcomes of the project aim and objective. Following that is **Evaluation Strategy** to discuss the different ways to evaluate the machine learning algorithms. Next, **Implementation** to describe how the models and the website was created. **Results and Evaluation** discusses the evaluations and the results of the algorithms. **Achievements and Future Work** discuss all the achievements of the objectives and the possibility of any future work.

Chapter 2

Literature Review

In this part of the chapter we are going to research the work done regarding the topic of the project. Each section covers different parts of the research by the authors.

2.1 Background

2.1.1 Greenhouse Gases (GHGs)

Human emissions of CO2 and other GHGs are a primary cause of climate change and present one of the world's most persistent challenges. This link between global temperatures and greenhouse gas concentrations, especially CO2, has been there throughout Earth's history [24]

The major greenhouse gases are Carbon dioxide (CO2), methane (CH4), nitrous oxide (N2O), hydrofluorocarbons (HFCs) and Sulphur hexafluoride (SF6). The most destructing gases of them all is Carbon Dioxide.

Weather phenomena (such as storms, droughts, and heatwaves); sea-level rise; and altered crop growth all have the ability to damage the environment and human health. The 5th Intergovernmental Panel on Climate Change (IPCC) report contains the most comprehensive overview of the potential impacts of climate change. [24].

CO2s and other GHGs follow a natural cycle, as seen in Figure 1, in which vast quantities of carbon flow back and forth from the atmosphere to the earth's surface. These processes have a tendency to maintain a moderately constant level of CO2 over time. [25].

FIGURE 1: Carbon Cycle [26]

To get perspective as to where to even start reducing the GHG emission, the author is going to find out the sectors (such as industrial, agriculture, Energy sector etc.) and countries responsible for this increase in GHGs.

2.1.2 Data Mining and Machine Learning

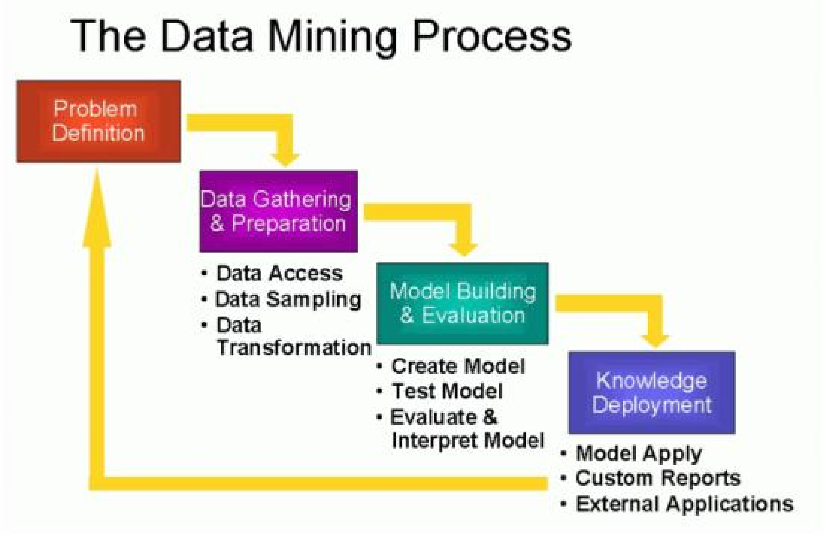
Data mining is the method of analyzing vast amounts of data for patterns that would be impossible to find by traditional research. Data mining employs statistical algorithms to segment data and calculate the likelihood of future events. [10]

To analyze massive data sets, data mining incorporates techniques from statistics and artificial intelligence (such as machine learning). Data mining is widely employed in industry, scientific research, and government protection. [14]

To get the best results from data, a variety of tools and techniques are needed. Among the most frequently used functions are:

- Data cleansing and preparation- A step in which inaccurate or corrupt data is detected and removed. [13]
- Machine learning- It is a process where the machine acquires the skills and knowledge by identifying and using preexisting knowledge [28]

- Regression— A method for predicting a variety of numeric values, such as revenues, temperatures, and so on, using machine learning on a dataset. [11]



The data mining process involves a series of steps to define a business problem, gather and prepare the data, build and evaluate mining models, and apply the models and disseminate the new information.

FIGURE 2: The Data Mining Process [23]

Machine learning is letting the computers to learn and consequently act the way humans do, improving its learning and knowledge over time autonomously. [12]

In Machine Learning there are three general categories, but for this project we are going to look into two:

Supervised machine learning can be used to make predictions about hidden or future data called predictive modeling. The algorithm develops functions that accurately predicts the output from input variables, such as predicting the market value of a home (output) from the square foot (input) and other inputs (type of construction, etc.). [12]

Two types of supervised learning are:

- **Classification**
- **Regression**

Supervised Learning Algorithm consists of k-Nearest Neighbor (kNN), Linear regression, Naive Bayes, support vector machine (SVM), logistic regression and gradient boosting.

In **unsupervised machine learning**, the algorithm is left on its own to find its input on its own. Discovering hidden patterns in data or a means to an end can be a goal in itself. This is also known as "feature learning" [12]

For our project we will be using three Supervised machine learning algorithm:

- **Linear Regression**: The linear regression method is used to determine the relationship between variables. Linear regression can be divided into two types: simple linear regression and multiple linear regression. The equation y=xβ+ϵ, is used to describe linear regression, where y is the independent variable and x is the dependent variable which is a continuous value. It is primarily concerned with the conditional probability distribution and interpretation. [20]

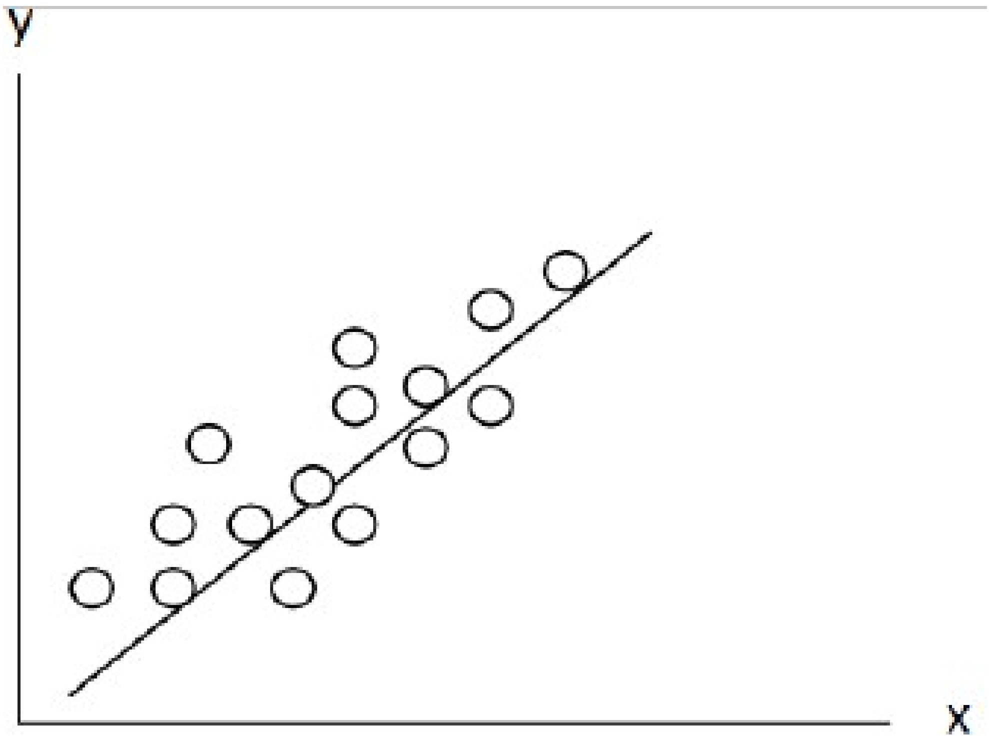


FIGURE 3: Linear Regression [20]

- **Support Vector Machine**: The aim of the support vector machine algorithm is to find the best hyperplane in more than two dimensions in order to determine how to classify the space. The hyperplane is derived from the maximum margin, which is the greatest distance between data points from both groups. [22]. Figure 4 depicts Support Vector Machine Algorithm.

- **Decision Trees**: The Decision Tree is a predictive model that uses observations from a dataset to calculate its target value. In a decision tree structure, the leaves represent names, the non-leaf sections represent features, and the branches represent feature conjunctions that lead to classification. [27]

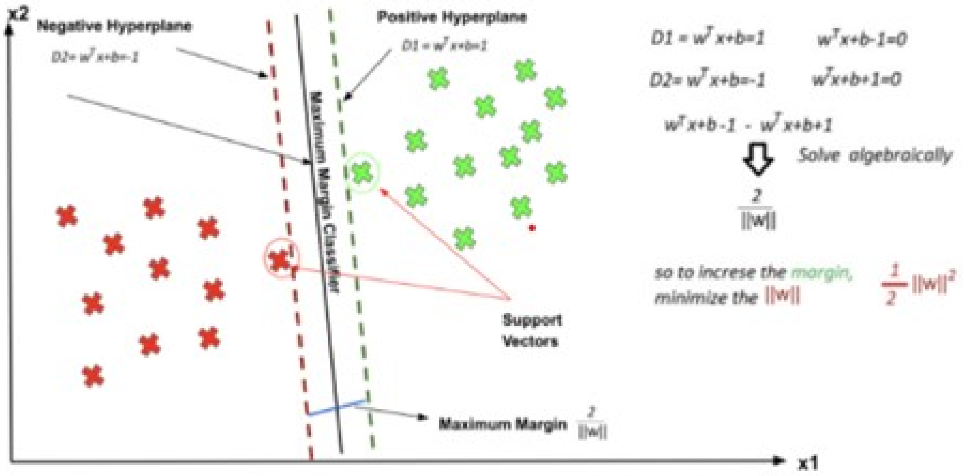

FIGURE 4: Support Vector Machine [22]

2.2 Related Works

2.2.1 Spatio-Temporal Analysis of Big Atmospheric Data

Cuzzocrea et al.[15] proposes an approach for supporting clustering-based analysis of big atmospheric data. In this paper the authors have researched the GHG's of the three European countries, namely United Kingdom, France and Italy. The authors had applied K-means clustering to the atmospheric big data. The aim of this paper was to produce a big data mining model which was used to analyze environmental data providing deeper understanding into high and low emitting sectors of GHG.

To achieve this, the author defined data workflow models which was used to analyze the environmental data. GHG's of several sectors were analyzed in order to find out where efforts and changes to reduce the emissions could be carried out. Then compared the emissions of the UK initially with the other countries. Also, over time, the GHG's of each country were investigated; in order to achieve that, a deeper insight was provided into the high and low emitting sectors [15].

The authors used the Cross-industry standard process for data mining (CRISP-DM) methodology in their paper, which is a standard methodology used to carry out data mining projects, and Weka Knowledge Flow, which is a graphical tool used to express the entire data mining process. CRISP-DM consists of the six phases depicted in Figure 5. This technique follows a cyclic pattern, and the ability to return to previous stages from specific points ensures that all input criteria are met completely.[15].

Critical Review: The approach towards the issue was very well designed and its use of the CRISP-DM methodology is well balanced and quite flexible. The data used for this paper by the authors was not too large, as it consists of information of only 3 countries, therefore it's not clear how this will handle huge datasets. The author decided to only use K-Means Clustering which may or may not be the best algorithm for this dataset, more algorithms should have been used to get better accuracy.

2.2.2 Prediction CO2 Emissions using Data Mining

Kunda et al. [21] examines Zambia's carbon-emissions-related policy provisions This paper also includes a time series study of CO2 emissions from 1964 to 2016 as well as a prediction for

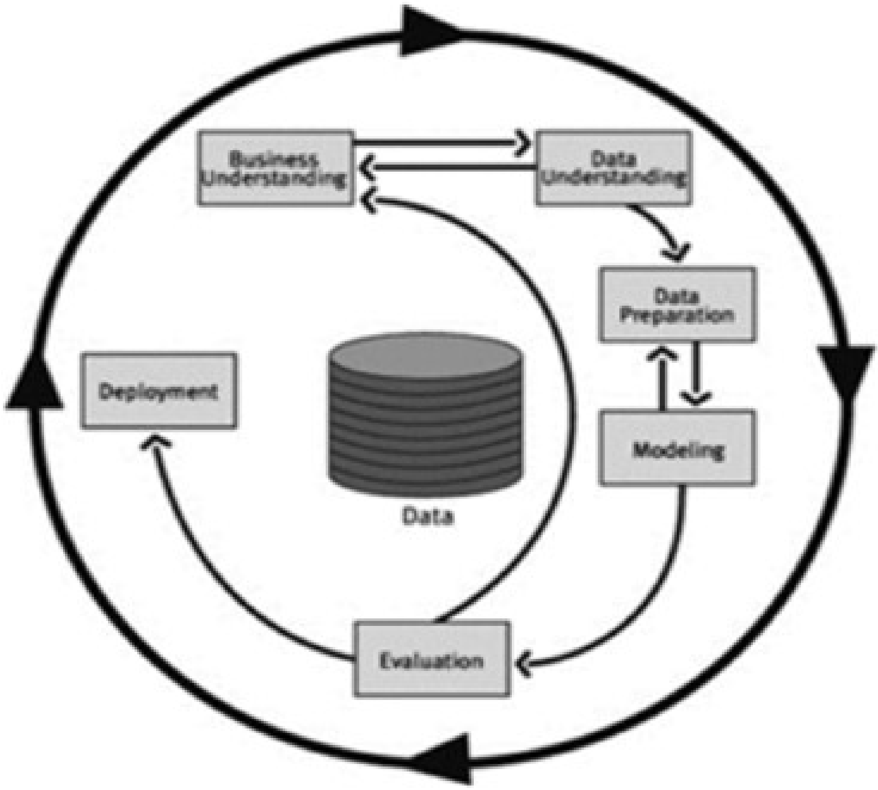

FIGURE 5: CRISP-DM Process [15]

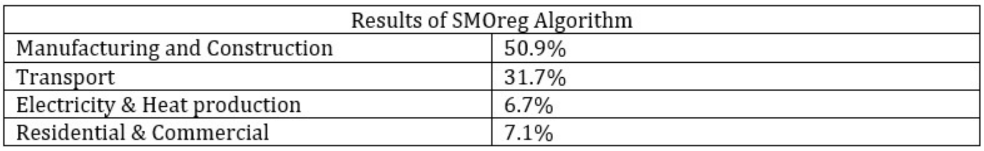
2021 using Weka Knowledge Flow as the data mining method. The dataset chosen for this was for the country of Zambia, as well as its transportation, manufacturing, and construction information. The aim of this paper was to determine the change in percentage contribution to carbon emissions from different sectors based on total fossil fuel combustion annually, as well as to determine which sector had the highest contribution of emissions and to make forecasts for the next five years based on carbon emissions from each sector. Furthermore, the authors hope that with this knowledge, policymakers can implement policies that will reduce CO2 emissions.

Data mining was used to predict and analyze the data. To analyze this data, the authors used SMOreg algorithm for time series.



Results of SMOreg Algorithm	
Manufacturing and Construction	50.9%
Transport	31.7%
Electricity & Heat production	6.7%
Residential & Commercial	7.1%

After analyzing the data, the future predictions from the year 2017-2021 shows a continuous increase in CO2 emissions of transport and manufacturing. [21]

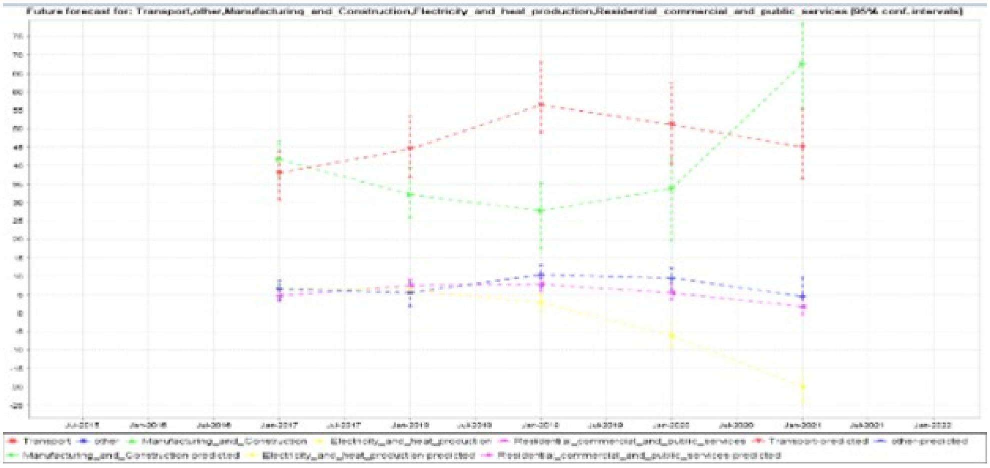


FIGURE 6: Zambia CO2 forecast [21]

Critical Review: The implementation of the algorithm appears satisfactorily accurate and gives the insight of the future forecast for the next five years . This paper had some drawbacks, the dataset used was only for one specific country and hence like the previous paper it fails to elaborate information regarding huge datasets.

2.2.3 Global Warming Prediction in India using Machine Learning

Hema et al. [16] analyzed global warming through global temperature and GHG gases in India using the data set from 100-150 years timeline. Their objective was to forecast the temperature and the GHG gases for the next 10 years and to create a graphical interface based on the results for easy understanding. The data was first collected and then later preprocessed. Linear Regression algorithm was selected for the paper after running tests on multiple algorithms such as Multiple Regression and Support Vector Regression on the preprocessed data. Linear Regression gets more prediction accuracy in comparison to the other algorithms (Hema, Pal, Loyer and Gaurav, 2019). After training with temperature and GHG gas data, pleasing accuracy results are obtained for temperature and GHG gas prediction. The prediction was accomplished by splitting the data for training and testing, and then creating an object to predict the test value. The object is used to forecast data for the next ten years. [16].

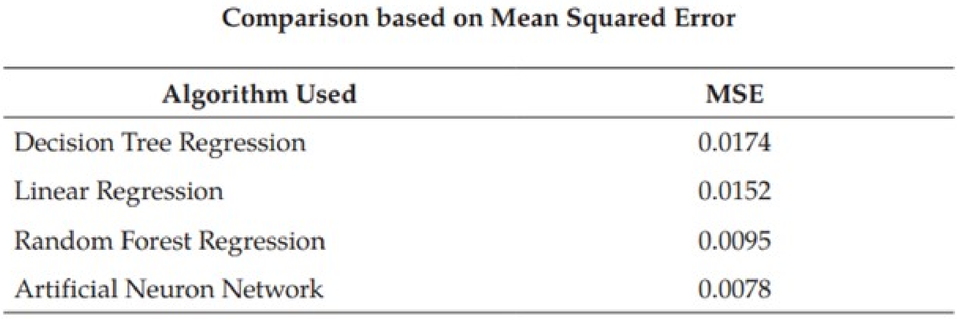
Critical Review: The approach seems to be detailed and well-presented. The author was able to predict and forecast the temperature for the next few years. The author could have used some more algorithms for comparison and selection. The model predicts only the average of temperature and the GHG concentration from the data set of approximate 150 years, the prediction could be far more accurate if the author would use much larger data set.

2.2.4 Relation Between Global Temperature and Concentrations of Greenhouse Gases

Kalra et al. [18] analyses two different datasets, one for global temperature and another for GHG concentrations. Using Linear Regression, Decision Trees, Random Forest, and Artificial Neural Network, the author discovers and models the relationship between two separate datasets spanning 65 years. The Keras Library was used for ANN, and the Sklearn library was used for the majority of the algorithms. The independent variables were the GHG gases and the dependent variable was the global temperatures.

The authors used the default hyperparameters for Linear Regression and Decision Trees. The authors discovered that using thirty trees yielded the lowest MSE for the Random Forrest Algorithm. Three layers were used for the Artificial Neural Network, with three input nodes, one output node, and two hidden nodes. The authors reasoned that using the Mean Square Error loss function would be preferable because it is a good predictor of how well the network models the given data. [18]

From the experiments conducted by the authors, they found out that the Artificial Neural Network performs in a way that is better than the other models performed on the same dataset.



Comparison based on Mean Squared Error

Algorithm Used	MSE
Decision Tree Regression	0.0174
Linear Regression	0.0152
Random Forest Regression	0.0095
Artificial Neuron Network	0.0078

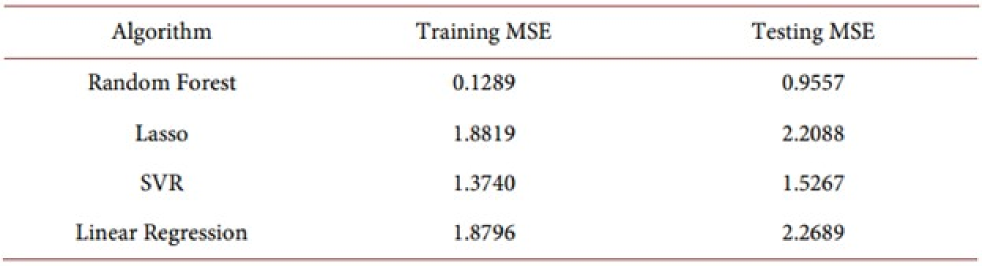
FIGURE 7: Comparison of Different Algorithms [18]

Critical Review: The approach of using different types of algorithms on large datasets is well experimented upon which in turn helps to decide the final algorithm to run the experiments on. Authors chose the best algorithm on the basis of mean square error which measures the squares of the errors. From the final algorithm chosen i.e. ANN, they were also able to calculate feature importance from which they were able to draw more conclusions.

2.2.5 Analysis of Global Warming Using Machine Learning

Zheng [29] compares the performance of several machine learning algorithms on the data. The algorithms used for the experiment included Linear Regression, Support Vector Regression and Random Forrest, these were used to build models which uses concentrations of different Greenhouse Gases to precisely predict the global atmosphere. The data chosen by the author was vast, it was from the past 800,000 years. This data was aligned using linear interpolation because the data was vast and there might have been missing values. For the three different machine learning algorithms, the parameters were altered to fit the data and produce accurate training results.

To measure the accuracy of the models, Mean Square Error (MSE) was used. The training and testing of the different algorithms show that the Random Forest creates the most accurate models as shown in Figure 8. Through machine learning the author confirms that the CO2 is the biggest contributor to temperature change [29]



Algorithm	Training MSE	Testing MSE
Random Forest	0.1289	0.9557
Lasso	1.8819	2.2088
SVR	1.3740	1.5267
Linear Regression	1.8796	2.2689

FIGURE 8: MSE of Each Algorithms [29]

Critical Review: The author uses a vast data source to predict the change in temperature which in turn gives far more accurate results. The implementation and proving of a point i.e. CO2 is the biggest contributor to temperature change was executed successfully. The author chose few machine learning algorithms for the experiment, however, more proven and accurate algorithms from the previous papers could be used such as XGBoost or Artificial neural Network which can produce better models.

2.3 Conclusion

After reading and researching through multiple papers and choosing the relevant papers for this experiment, I have decided to choose the following Machine Learning Algorithms, these are all supervised algorithms.

- **Linear Regression**
- **Support Vector Machine**
- **Decision Tree**

I learned about the different techniques before settling on the above Machine Learning Algorithms, and hence Linear Regression was chosen on the basis of its popularity and it is the most common regressor algorithm in machine learning. Most of the papers have used linear regression, for example in the papers by **Hema et.al** [16], **Kalra el al.** [18] and **Zheng** [29], tested their dataset on linear regression and their results have good accuracy. Support Vector Machine algorithm was chosen as the second algorithm mainly because it provides the option of many hyperparameters which can be altered in order to obtain the best accuracy from the model, also, from section 2.2.3, the author used the Support Vector Machine algorithm as one of the Machine Learning Algorithms to compare the different algorithms along with Linear Regression. The final algorithm Decision Tree was decided as it also has different parameters in it, for instance, the depth of the tree, which can be meddled with to get high accuracy on the model.

There are a lot of algorithms which could be used to experiment the Middle Eastern dataset with, for instance, Artificial Neural Network, which proved to be a great algorithm with the lowest Mean Square Error as shown is section 2.2.4, however, ANN requires a huge dataset to test its model and this experiments dataset doesn't suffice its requirement.

2.4 Research Gaps

There hasn't been little to no research conducted on the dataset of the Middle Eastern countries.

2.5 Challenges

The challenge of this project is to use the dataset and run the different machine learning algorithms. Each algorithm has different methods, for instance, the different methods and their parameters for each Machine learning algorithm, which makes it hard to switch around and keep track of different functionalities of each algorithm. Another challenge will be finding out which country is responsible for the highest emission of Greenhouse gases in middle east.

Chapter 3

Requirements Analysis

This chapter recognizes the Functional and the Non-functional requirements of the system with its priorities. These requirements are vital for the project as it ensures the development of the system.

The requirements are categorized on the basis of priority as:

- **Must Have**: These requirements are essential for the successful implementation of this project.
- **Should Have**: These requirements are essential and should be included in the system it possible.
- **Could Have**: These requirements are optional and have a small impact if left out.

3.1 Functional Requirements

Functional requirements are functions that developers must implement to enable users to complete their tasks. These requirements describe the system behavior.

FR No.	**Requirements Description**	**Priority**
1	The data should be preprocessed	Must
2	The system should be able to analyze the dataset	Must
3	The system should implement Linear Regression	Must
4	The system should implement Support Vector Machine	Must
5	The system should implement Decision Tree	Must
6	The system should generate accurate results from the model	Must
7	The GUI should be functional	Must

3.2 Non-Functional Requirements

The Non-functional requirements describes the constraints and the general characteristics.

NFR No.	**Requirements Description**	**Priority**
1	The system should be scalable	Should
2	The system should be able to run on any OS	Could
3	The user should be able to read the presented data	Must
4	The GUI should be easy to use	Should

3.3 Functional and Non-Functional Analysis

Evaluation strategy is used to find out whether the aims and objectives of the project have been satisfied. Hence, it is necessary to evaluate and test the usability, functionality of the system.

3.3.1 Functional Requirements analysis

- **The data should be preprocessed**
  To evaluate this, the author must preprocess the data to run machine learning algorithms and generate models.
- **The system should be able to analyze the Dataset**
  To evaluate this, the author needs to make sure that the system testing the dataset is correct and is in accordance to the topic.
- **The system should implement Linear Regression**
  To evaluate this, the author needs to create a model using Linear Regression.
- **The system should implement Support Vector Machine**
  To evaluate this, the author needs to create a model using Support Vector Machine.

- **The system should implement Decision Tree**

  To evaluate this, the author needs to create a model using Decision Tree.

- **The System should generate accurate results from the model**

  This will be evaluated by making sure that the system generates accurate results for the dataset using different machine learning techniques.

- **The GUI should be functional**

  This will be evaluated by making sure that the created website is tested properly for its functionality.

3.3.2 Non-Functional Requirements

- **The system should be scalable**

  The system should be designed in such a way that there's a scope for improvement and future work.

- **The System should be able to run on any OS**

  To ensure this, the author need to make sure that the system designed runs on any type of operating system i.e. Windows 10, Windows 7 or MacOS

- **The user should be able to read the presented data**

  The data presented by the system can be read by all the age groups.

- **The GUI should be easy to use** To ensure that it works the author needs to make sure that the GUI created can be used by all age groups.

3.4 Research Question

One of the main questions that need to be answered through this dissertation is, which Machine Learning algorithm achieves the best accuracy on the dataset. These various algorithms were selected on the basis of the research papers on Greenhouse gases and its results.

The next question that needs answering is, which country and its sector is responsible for high GHG emissions.

Chapter 4

Evaluation Strategy

After the creation of the models and predicting the testing values with the actual, we need to interpret the models reliability. It is possible in many ways, but for this experiment we will look into the following:

- Coefficient of Determination (R^2)
- Mean Square Error (MSE)
- Mean Absolute Error (MAE)
- Explained Variance

4.1 Coefficient of Determination (R^2)

R^2 is a statistical measure that represents the proportion of a dependent variable's variance explained by an independent variable or variables in a regression model [17]. The R^2 value ranges from 0 to 1, and can be easily interpreted; for example, R^2: 0.75 indicates that 75% of the dependent variable is predictable.

$$R^2 = 1 - \frac{SS_{Regression}}{SS_{Total}} = 1 - \frac{\sum_i (y_i - \hat{y}_i)^2}{\sum_i (y_i - \bar{y})^2}$$

$SS_{Regression}$: Residual sum of squares.

SS_{Total}: Total sum of squares.

4.2 Mean Squared Error (MSE)

Mean Squared Error (MSE), also known as Mean Squared Deviation (MSD), is a measurement of the sum of the squares of the error, or the average squared difference between the real and predicted values. Most regression algorithms evaluate the outcomes using Mean Squared Error.

$$\mathbf{MSE} = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2$$

y_i: Actual Value

$\hat{y}_i$: Expected Value

4.3 Mean Absolute Error (MAE)

In statistics, the mean absolute error (MAE) is a measure of the difference in errors between paired observations describing the same phenomenon [17]. It is simply defined as the average of all absolute errors. MAE values range between 0 and ∞, with a lower value indicating a better model.

$$\mathbf{MAE} = \frac{\sum_{i=1}^{n}|y_i - x_i|}{n}$$

y_i: Actual Value

x_i: Expected Value

4.4 Explained Variance

Explained Variance also known as Explained Variation is a measurement of the difference between actual data and a model. Explained variance is similar to Coefficient of Determination, the main difference between the two is that Mean Error is being subtracted in Explained Variance. If the Mean Error is equal to 0, then R^2 is equal to Explained Variance.

$$\textbf{Explained Variance Score} = 1 - \frac{Var(y - \hat{y})}{Var(y)}$$

$Var(y - \hat{y})$: Variance of predicted error

$Var(y)$: Variance of actual values

Chapter 5

Implementation

5.1 Tools Used

5.1.1 Programming Language

For the project, Python version 3.8 [7], was used as the programming language of choice. Python is recognized as a high-level and general purpose programming language. Python is very easy to write, read and understand. There are various libraries that are supported in python. Although its usability and readability are a huge factor in the decision for choosing the programming language, but it is not memory efficient as it uses a lot of memory to run a program and hence slowing down the process. As the Dataset being used for the project is not that huge, it shouldn't be much of a problem.

5.1.2 Libraries

Python has vast libraries support, so for the project, ***Numpy*** Library [5] was used for the preprocessing stage to get rid of zeros in the dataset. ***Pandas*** Library [6] was used to read the Comma-separated values and convert it into a ***DataFrame*** [2]. To visualize the results ***Matplotlib*** Library [3] was used to show different types of graphs like Scatter Plot and Line Graph. To use the different algorithms, create its models and get metrics for assessing the errors, ***Scikit-Learn*** Library [9] was used.

5.1.3 Hardware

A good hardware is required run machine learning algorithms and to create models because it requires a lot of memory and CPU power. The hardware used for the implementation of all the objectives in order for it to work perfectly are as follows:

- Processor: Intel Core i7-9750H CPU @ 2.60 GHz
- RAM: 16 GB
- Operating System: Windows 10 Home 20H2

5.2 Dataset

5.2.1 Dataset Collection

The data was acquired from a Open Source website [1] consisting of different emissions recorded from the year 1990 to 2016 from the Middle Eastern countries.

The table 5.1 shows the list of attributes in the dataset, a description of the attributes, and whether the attribute is required or not for the evaluation.

Attribute Name	**Description**	**Required**
Country	Country Names	Yes
Data Source	The source of the data	No
Sector	The various sectors of the country	Yes
Gas	The different types of Gases	No
Unit	The unit measurement of the gases	No
Years	Recorded GHG emissions of the years from 1990 to 2016	Yes

Table 5.1: Attribute Description

The removed attributes carry no weight in regards for the evaluation on the Dataset and hence they were removed.

5.2.2 Dataset Preparation

Prior to the preprocessing of the dataset, the dataset consisted of 930 rows and 31 columns, out of which, 26 columns consists of the years from 1990-2016 with the values of Greenhouse Gases.

To prepare the data, all the rows with 0 were first converted to 'NaN' (Not a Number) type values to easily remove them and then convert back the 'NaN' values to 0, if any, using the Numpy Library in Python.

```
data = data.replace(0, np.nan)
data = data.dropna(how='any', axis=0)
data = data.replace(np.nan, 0)
```

Originally, the Year attributes in the Dataset started from the year 2016 all the way till 1990. To make it readable and also to make a model systematically, I decided to reverse the columns in order.

```
test = test[test.columns[::-1]]
```

5.3 Machine Learning Algorithms

After the Dataset has been preprocessed according to the requirements for the Machine Learning Algorithms, we are going to explore the Three Algorithms for the experiment.

5.3.1 Linear Regression

To create a Linear Regression model, the Dataset was first preprocessed to meet the requirements for the model i.e., removing the zeroes from the rows. As a part of preprocessing the data, I also removed the columns ”Country” and ”Sector” for the exact reason that it hinders the creation of the model, and to create one, we just need the numerical values.

The model learns from the Dataset by dividing it into two variables i.e., Independent variable denoted by ’X’ and Dependent variable denoted by ’y’. The independent variable consists of the GHG data from the year 1990 to the year 2015 whereas the dependent variable consists of GHG data from the year 2016.

```
X = test.drop([’2016’], axis=1)
y = test[’2016’]
```

These divided datasets are split into two i.e., 80% training data and 20% testing data using the ***train_test_split*** method from the Scikit-Learn library [9]. The model is then trained using both the independent and dependent training datasets. The model created can now be used to make predictions.

```
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.2)
model.fit(X_train, y_train)
```

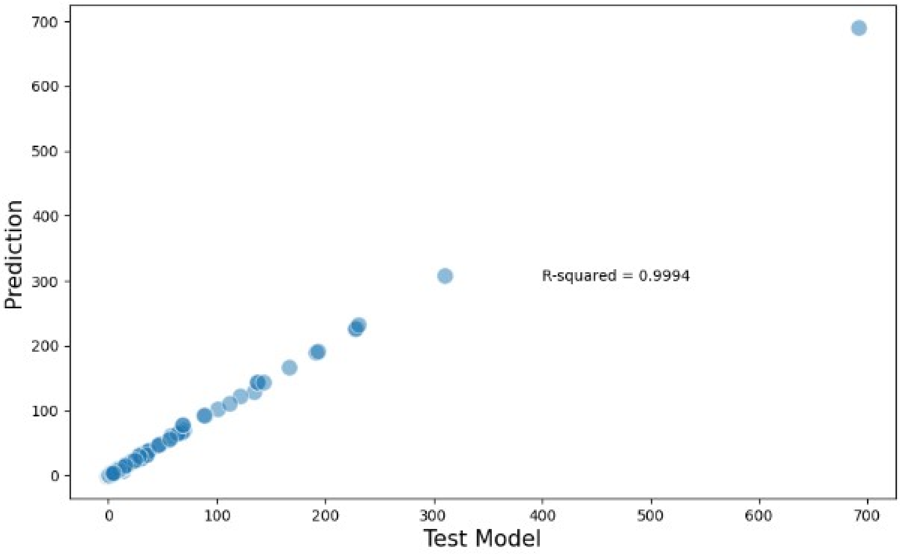


FIGURE 9: Test Model vs Prediction of Linear Regression

Figure 9 shows the graph for Test Model vs Prediction where it shows how accurate the created model is. The Test Model contains the GHG values of the year 2016 and the prediction is what the model predicts values on the basis of the Testing Dataset. The accuracy depicted from the graph is **99.94%**. More description of the results is shown in table 5.2.

Results	
Evaluations	Accuracy
Mean Square Error (MSE)	3.49
Mean Absolute Error (MAE)	0.7965
Variance Score	0.9994
R^2	99.94%

TABLE 5.2: Linear Regression Results Table

5.3.2 Support Vector Machine

To create Support Vector Machine model, the Dataset was similarly preprocesssed like the one in Linear Regression to meet the requirements for the model.

SVM model learns from the Dataset divided into Independent variable and Dependent variable denoted by 'X' and 'y'. The independent variable consits of the GHG data from the year 1990 to the year 2015 while the dependent variable consists of GHG data from the year 2016.

```
X = data[
    ['1990', '1991', '1992', '1993', '1994', '1995', '1996', '1997', '1998',
    '1999', '2000','2001', '2002', '2003', '2004', '2005', '2006', '2007',
    '2008', '2009', '2010', '2011','2012', '2013', '2014', '2015']]
y = data['2016']
```

These divided datasets are split into two i.e., 70% training data and 30% testing data using the Scikit-Learn package ***train_test_split*** method. A ***Random State*** of 50 is selected after changing comparing it with other states as it gives us the most optimal result. The random state helps decide the splitting of the dataset.

```
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.3,
random_state=50)
```

To get a good model, I decided to use the ***GridSearchCV*** method provided from the Scikit-Learn package, it helped me run different hyperparameters options, without it, I would have to create a manual loop to check each hyperparameter to get an optimum accuracy. In SVM there are two parameters **'C'** which denotes misclassification, and **'Gamma'** which determines how far a plausible line of separation's calculation is affected, excluding 'Kernel' which I decided for it to be default i.e., 'rbf'. A model is created after an optimum parameter is selected.

```
grid_parameter = {'C': [0.1, 1, 10, 100], 'gamma': [1, 0.1, 0.01, 0.001]}
grid = GridSearchCV(SVR(kernel='rbf'), grid_parameter, verbose=2)

grid.fit(X_train, y_train)
```

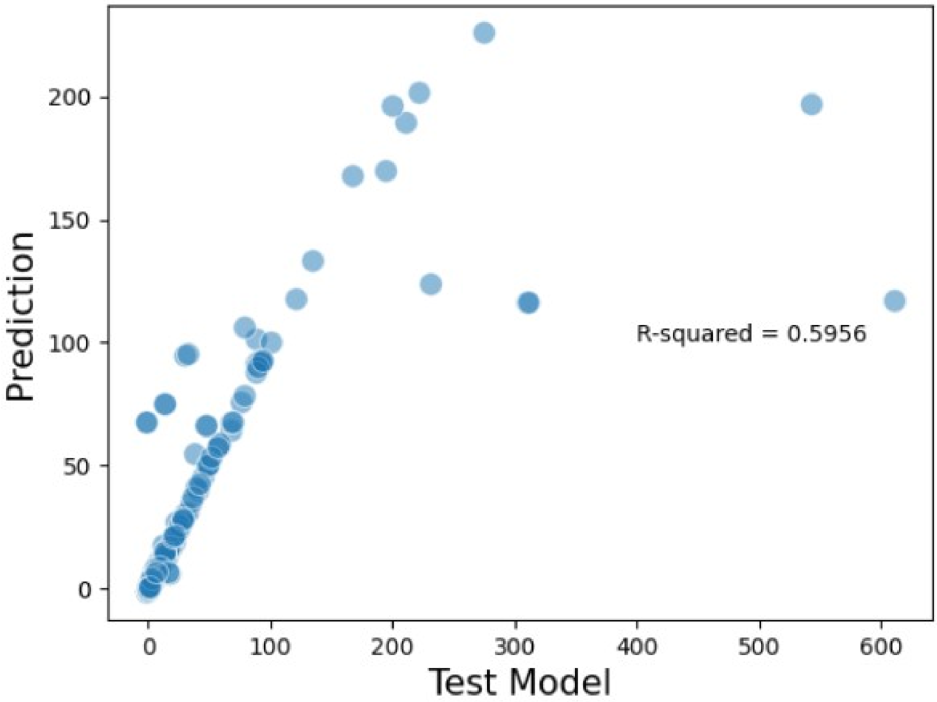

FIGURE 10: Test Model vs Prediction of Support Vector Machine

Above is the graph for Test Model vs Prediction where it shows how accurate the created model is. The Test Model contains the GHG values of the year 2016 and the prediction is what the model predicts values on the basis of the Testing Dataset. The accuracy depicted from the graph is **59.56%**. A much more detailed information is depicted in table 5.3

Results	
Evaluations	Accuracy
Mean Square Error (MSE)	2108.67
Mean Absolute Error (MAE)	8.9998
Variance Score	0.5991
R^2	59.56%

TABLE 5.3: SVM Results Table

5.3.3 Decision Tree

The Decision Tree model was constructed by preprocessing the data as stated in section 5.2.2. Further preparation was done to create the model, the columns named ”Countries” and ”Sector” were removed because it is not either of the types of categorical or numerical and hence it would hinder the creation of the model.

The Dataset was divided into Independent and Dependent variable denoted by ’X’ and ’y’ comprising of the GHG data from the year 1990 to the year 2015 and the GHG data from the year 2016 respectively.

```
X = data[
    ['1990', '1991', '1992', '1993', '1994', '1995', '1996', '1997', '1998',
    '1999', '2000','2001', '2002', '2003', '2004', '2005', '2006', '2007',
    '2008', '2009', '2010', '2011','2012', '2013', '2014', '2015']]
y = data['2016']
```

These variables are then split into two, 70% training data and 30% testing data using the ***train_test_split*** method from the Scikit-Learn library. A Random state of 50 is chosen as the parameter as it helps the splitting of the dataset. This was chosen after creating and running the model multiple times.

```
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.3,
random_state=50)
```

To build the perfect model, I experimented with the parameters of the ***DecisionTreeRegressor*** by changing its ’max_depth’ and creating multiple models to check the accuracy on each of the ’max_depth’. After experimenting, I came to a conclusion that after a max_depth of 5, there seems to be little to no change in the overall accuracy of the model. It is depicted clearly in Figure 11.

For the accuracy of the model, I chose Depth being equal to 20 as it gives the highest accuracy from the rest. The result of the model is depicted in the table below. Also, the visualization of the tree is shown in appendix.

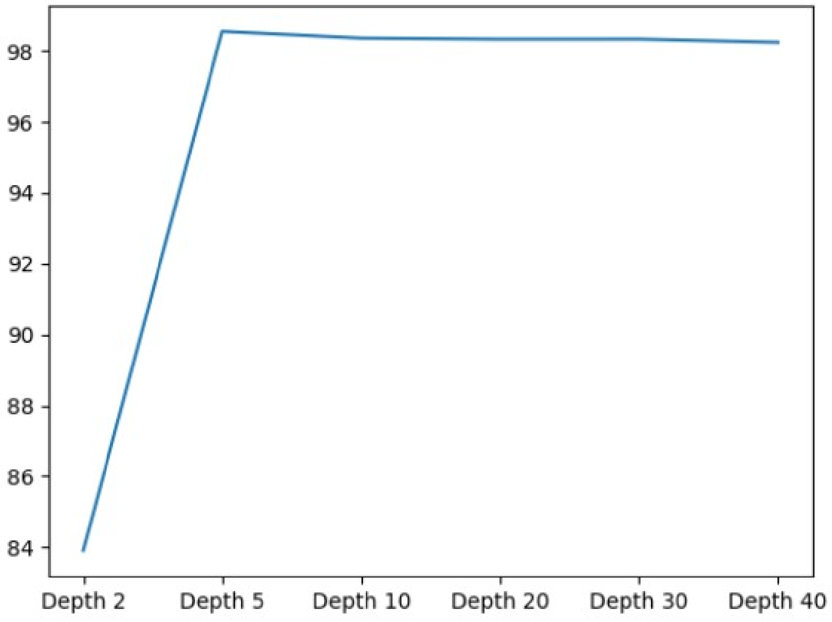

Figure 11: Change in accuracy vs the Depth

The Figure 12 shows the graph for Test Model vs Prediction for the Depth of **5** where it shows the accuracy of the model. The Test Model contains the GHG values of the year 2016 and the prediction is what the model predicts values on the basis of the Testing Dataset. The accuracy depicted from the graph is **98.38%**. A much more detailed information is depicted in table 5.4.

Results	
Evaluations	Accuracy
Mean Square Error (MSE)	84.36
Mean Absolute Error (MAE)	1.6486
Variance Score	0.9838
R^2	98.38%

Table 5.4: Decision Tree Results Table

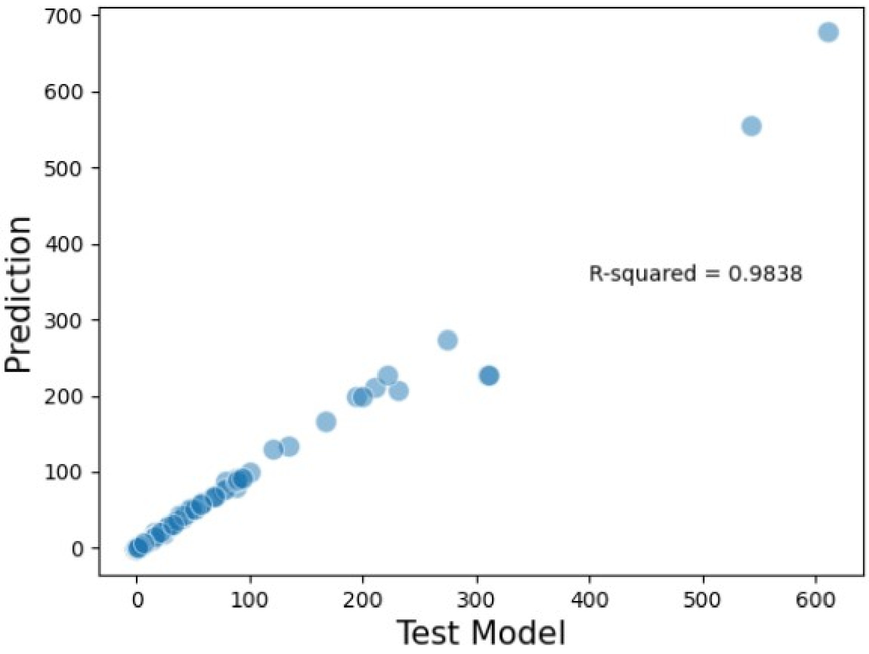

Figure 12: Test Model vs Prediction of Decision Tree

5.4 Sector

Finding out sectors within the country which are responsible for high emission can help the people who would like to take action for the same in order to reduce the overall emission.

To find out which sector in a country is responsible for its high emission, I firstly processed the data i,e., I removed the columns 'Data source' and 'Unit' for the reason that they were redundant and held no real value.

```
data.drop('Data source', inplace=True, axis=1)
data.drop('Unit', inplace=True, axis=1
```

I then moved on to selecting only those rows which have 'All GHG' because the data initially contained mixed gases constituting of 'N20', 'CO2', 'CH4' and 'F-Gas'. 'All GHG' consisted of all theses gases and hence opting to choose only this was a good option. 'Total including LUCF' and 'Total excluding LUCF' was removed from the dataset because it consisted of the total GHG values of all the sectors including and excluding 'Land-Use Change and Forestry' which is not a good estimate to find out the exact sector in a country responsible for high emission.

```
data = data.loc[data['Gas'] == 'All GHG']
data = data.loc[data['Sector'] != 'Total including LUCF']
data = data.loc[data['Sector'] != 'Total excluding LUCF']
```

Now that we have filtered data with only the right columns and rows, we can proceed to sum each rows with sector's GHG values and put the values in a new column called 'GHG'.

```
data["GHG"] = data.sum(axis=1)
```

I then proceed to group the countries with GHG values to convert it into a list, because in a DataFrame, we cannot group by multiple columns and so therefore I decided to put the calculated GHG values in a list and then locate the rows which have the same values as in the list.

```
countriesGHG = data.groupby(’Country’, as_index=False)[’GHG’].max()

listOfGHG = countriesGHG[’GHG’].tolist()

filtered = data.loc[data[’GHG’].isin(listOfGHG)]
```

The data we have right now still needs to be filtered. This new data has 20 rows with unique countries and its sectors which was selected on the basis of the highest total emission over the years from 1990 to 2016 along with the individual GHG values of each year. I decided to remove the individual GHG values of each year to get a much cleaner data.

```
filtered = filtered.drop([’1990’, ’1991’, ’1992’, ’1993’, ’1994’, ’1995’,
’1996’, ’1997’, ’1998’, ’1999’, ’2000’, ’2001’, ’2002’,’2003’, ’2004’,
’2005’,’2006’, ’2007’, ’2008’, ’2009’, ’2010’,’2011’, ’2012’,’2013’
,’2014’, ’2015’, ’2016’, ’Gas’], axis=1)
```

Dataset with Sectors		
Country	**Sector**	**GHG**
Algeria	Energy	3121.63
Bahrain	Energy	570.35
Djibouti	Agriculture	18.21
Egypt	Energy	3975.08
Iran	Energy	12604.98
Iraq	Energy	2709.41
Israel	Energy	1522.25
Kuwait	Energy	1615.02
Lebanon	Energy	411.46
Libya	Energy	2927.94
Malta	Bunker Fuels	66.10
Morocco	Energy	1097.53
Oman	Energy	938.02
Qatar	Energy	1140.15
Saudi Arabia	Energy	8685.04
Syria	Energy	1645.66

Tunisia	Energy	571.58
United Arab Emirates	Energy	3694.03
Yemen	Energy	435.37

Table 5.5: Country and Sectors Table

The table 5.5 shows the filtered data with the unique countries, its sector and the total GHG values from the years.

These values from the table 5.5 is better depicted by a graph. This graph was created using the **Matplotlib** Library.

```
filtered.set_index(['Country', 'Sector']).plot.bar(color='royalblue')
plt.xlabel('Country—Sector', size=15)
plt.ylabel('GHG Value', size=15)
plt.title('Countries and its Sector responsible for high GHG', size=15)
plt.grid(color='#95a5a6', linestyle='——', linewidth=2, axis='y', alpha=0.7)
figure(figsize=(12, 5), dpi=2060)
plt.rcParams["figure.figsize"] = (12,5)
```

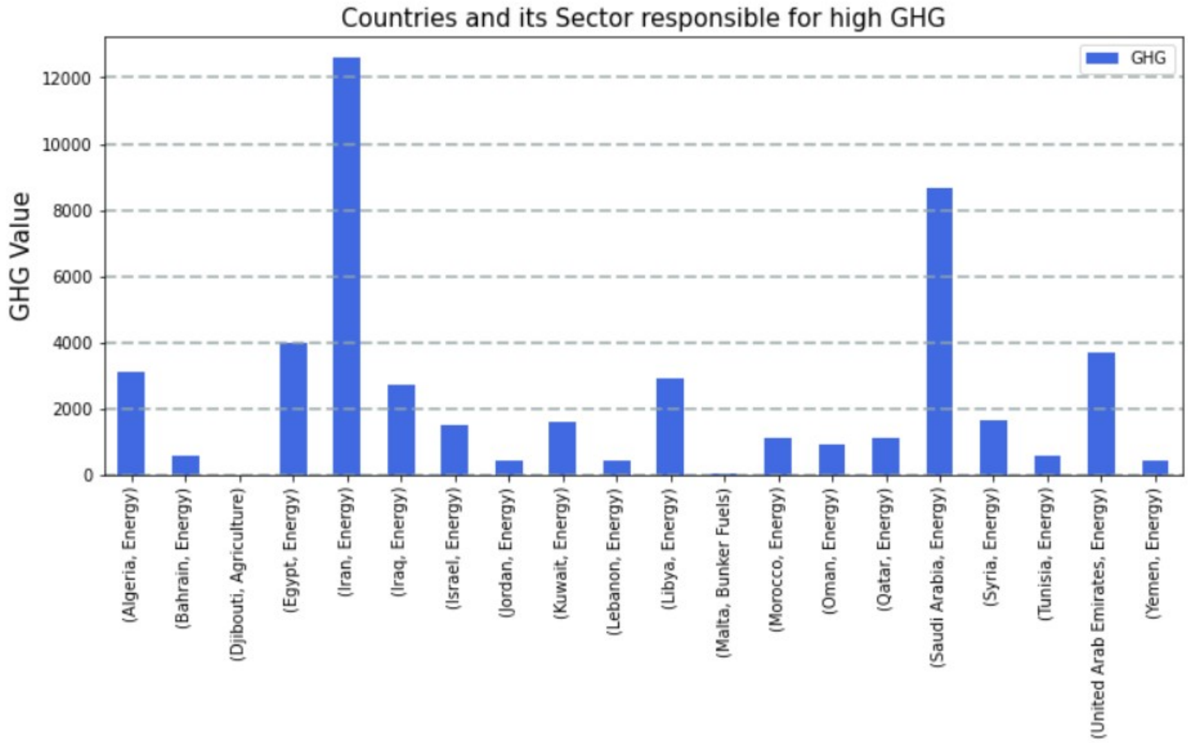

Figure 13: Country and its Sector Graph

5.5 GUI

5.5.1 React

In order to meet the requirements for the implementation of GUI, React JS [8], a javascript library, was used to create a front end website to show the graphs of the machine learning algorithms, and also a study on the dataset where it shows the Sectors of the Country in the Middle East with the highest level of GHG values.

I had no previous experience on development on React hence I decided to learn React from scratch. It had a shallow learning curve as it was mainly based on Javascript and due to my prior experience in Javascript, I was able to comprehend and grasp the knowledge of React effortlessly. The development process with React is very efficient, as many of its components are reusable and hence it boosts productivity and, its quick rendering helps improve the overall website performance.

5.5.2 Server-Side Execution

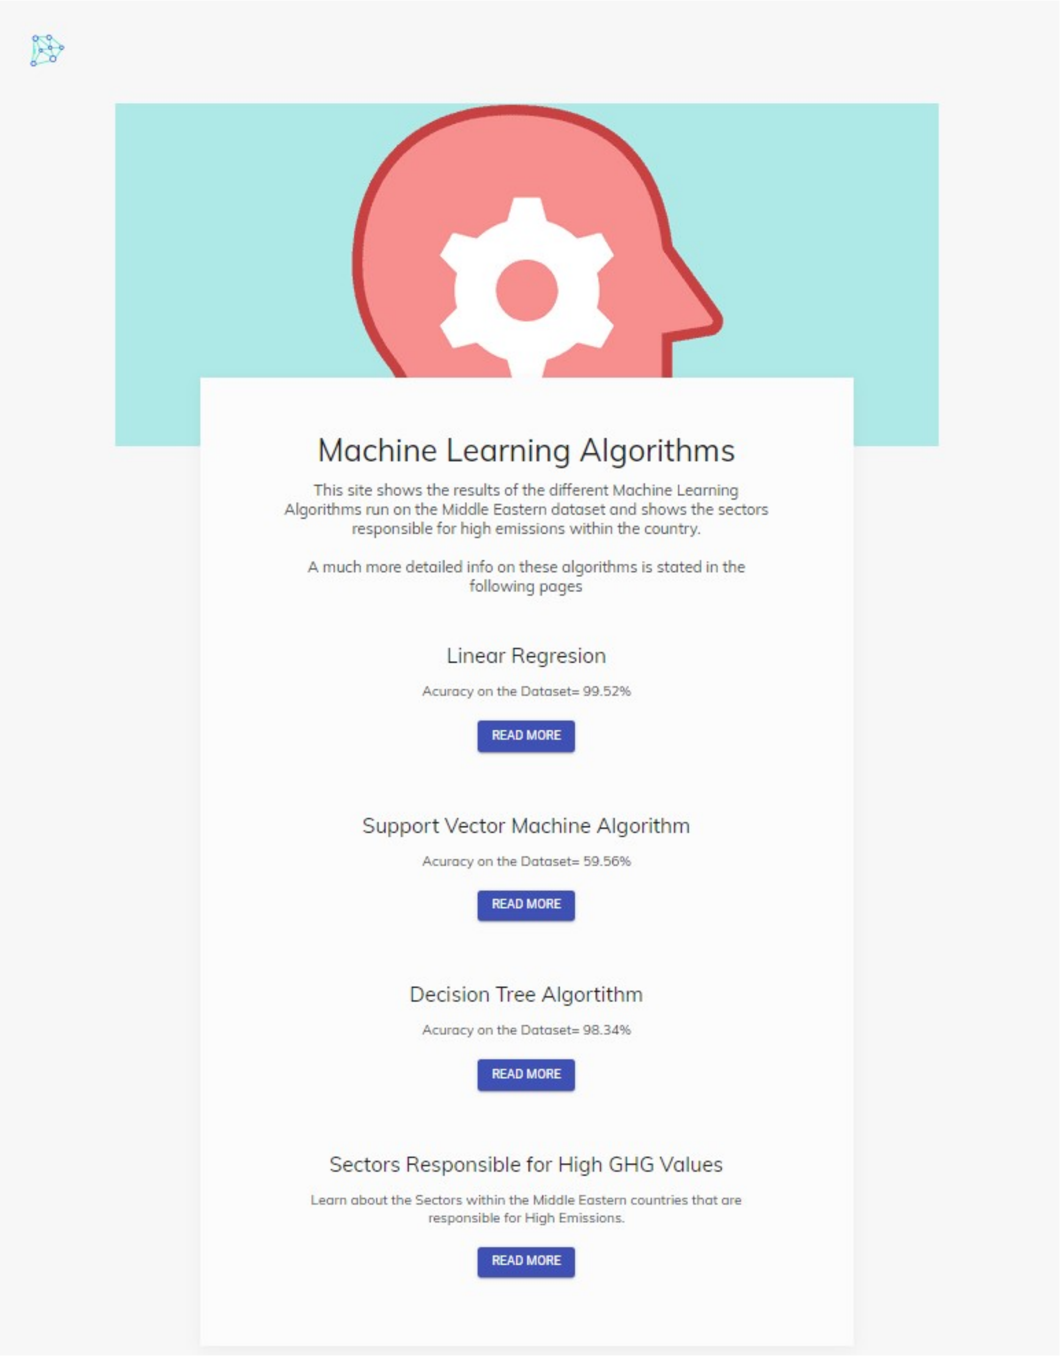
The testing of the application was done by checking each process of development and for that reason, the React application uses **node.js** which helps running of the server-side of the application locally. With the help of node, compilation of the react application into a single file using webpack and several node modules is easily executed [19].

5.5.3 Version Control

For the Entire development process of the React Application, Git was used as the version control and the project was recorded in Github i.e., the files and code. Github provides a great backup, it helps to rollback to a previous version of the project easily.

5.5.4 Frontend Implemented

The user of the web application is first introduced to the home page which is shown in Figure 14.



Machine Learning Algorithms

This site shows the results of the different Machine Learning Algorithms run on the Middle Eastern dataset and shows the sectors responsible for high emissions within the country.

A much more detailed info on these algorithms is stated in the following pages

Linear Regresion

Acuracy on the Dataset= 99.52%

Support Vector Machine Algorithm

Acuracy on the Dataset= 59.56%

Decision Tree Algortithm

Acuracy on the Dataset= 98.34%

Sectors Responsible for High GHG Values

Learn about the Sectors within the Middle Eastern countries that are responsible for High Emissions.

Figure 14: Home Page

The user of the website can access and learn either about the three Machine Learning algorithms or find out about the Country and its Sector responsible for high GHG emissions.

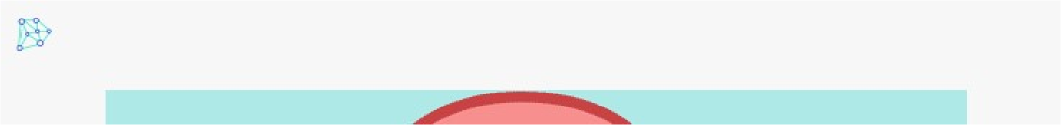


Figure 15: Home Button

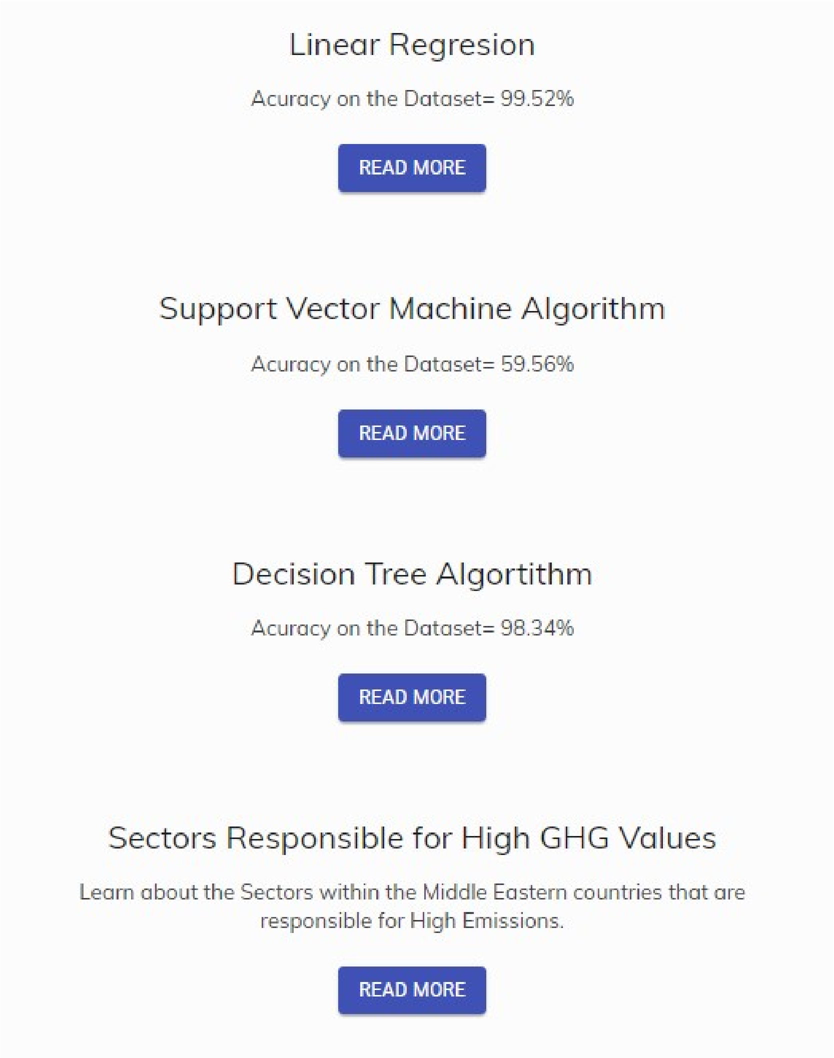
The figure 15 shows the home button on the top left side of the page. The user can go home from any of the pages the user visited before after clicking the button on the navigation bar.



Linear Regresion

Acuracy on the Dataset= 99.52%

Support Vector Machine Algorithm

Acuracy on the Dataset= 59.56%

Decision Tree Algortithm

Acuracy on the Dataset= 98.34%

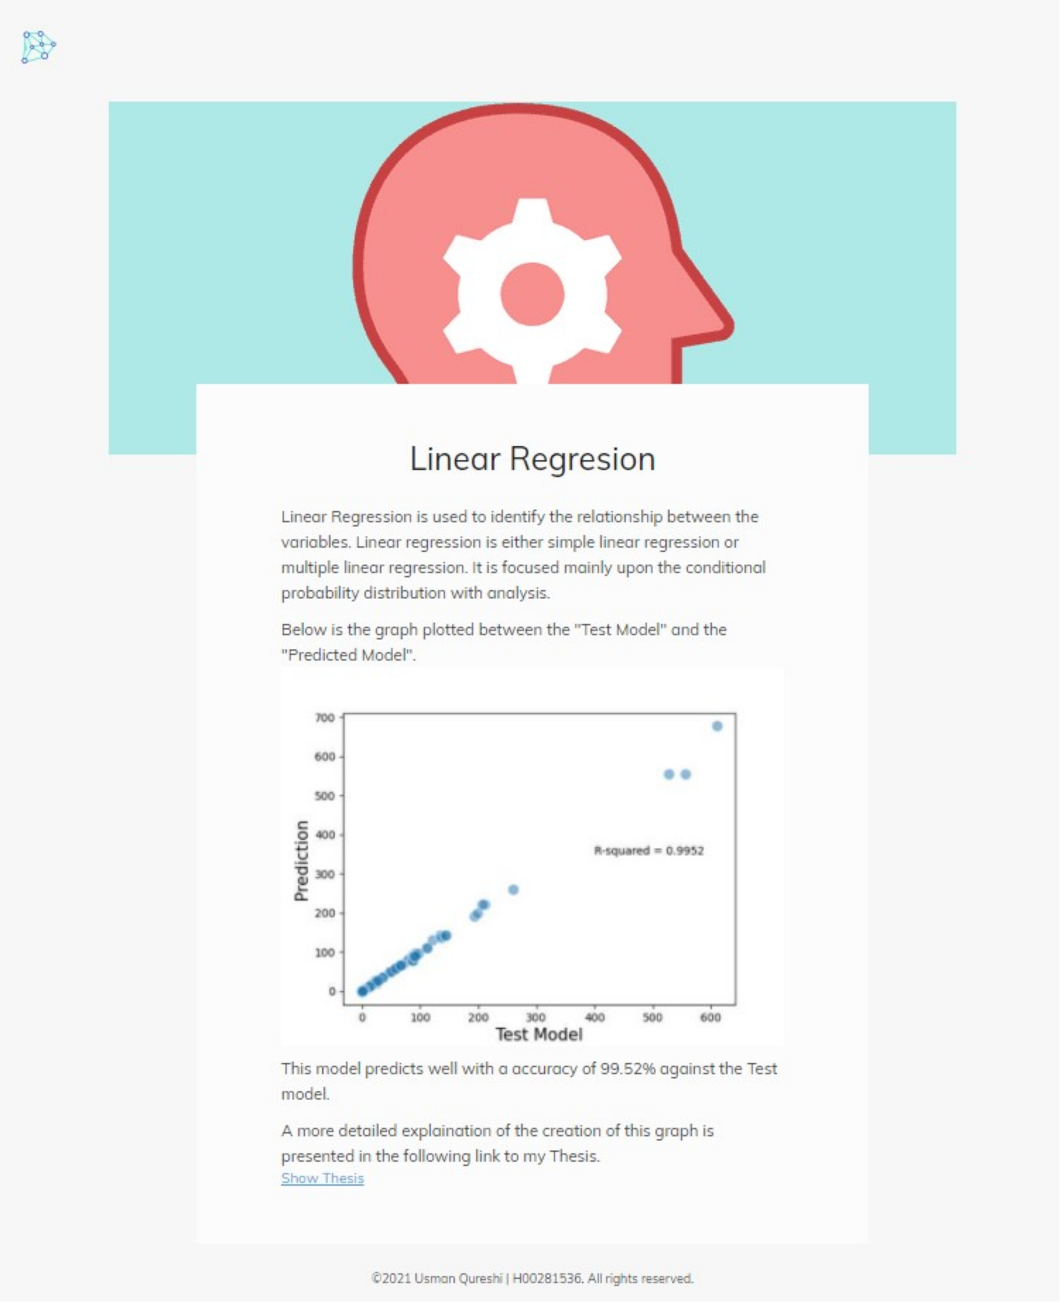
Sectors Responsible for High GHG Values

Learn about the Sectors within the Middle Eastern countries that are responsible for High Emissions.

Figure 16: Read More Button

The figure 16 shows the ”Read More” buttons which directs the user to the page they wish to learn more about.

After the user clicks on the first link about Linear Regression, the user is directed to the Linear Regression page which is shown in Figure 17 which holds information about the implemented Machine Learning algorithm with a reference link to this dissertation paper if the user wants to learn more about its implementation.



Linear Regresion

Linear Regression is used to identify the relationship between the variables. Linear regression is either simple linear regression or multiple linear regression. It is focused mainly upon the conditional probability distribution with analysis.

Below is the graph plotted between the "Test Model" and the "Predicted Model".

This model predicts well with a accuracy of 99.52% against the Test model.

A more detailed explaination of the creation of this graph is presented in the following link to my Thesis.
Show Thesis

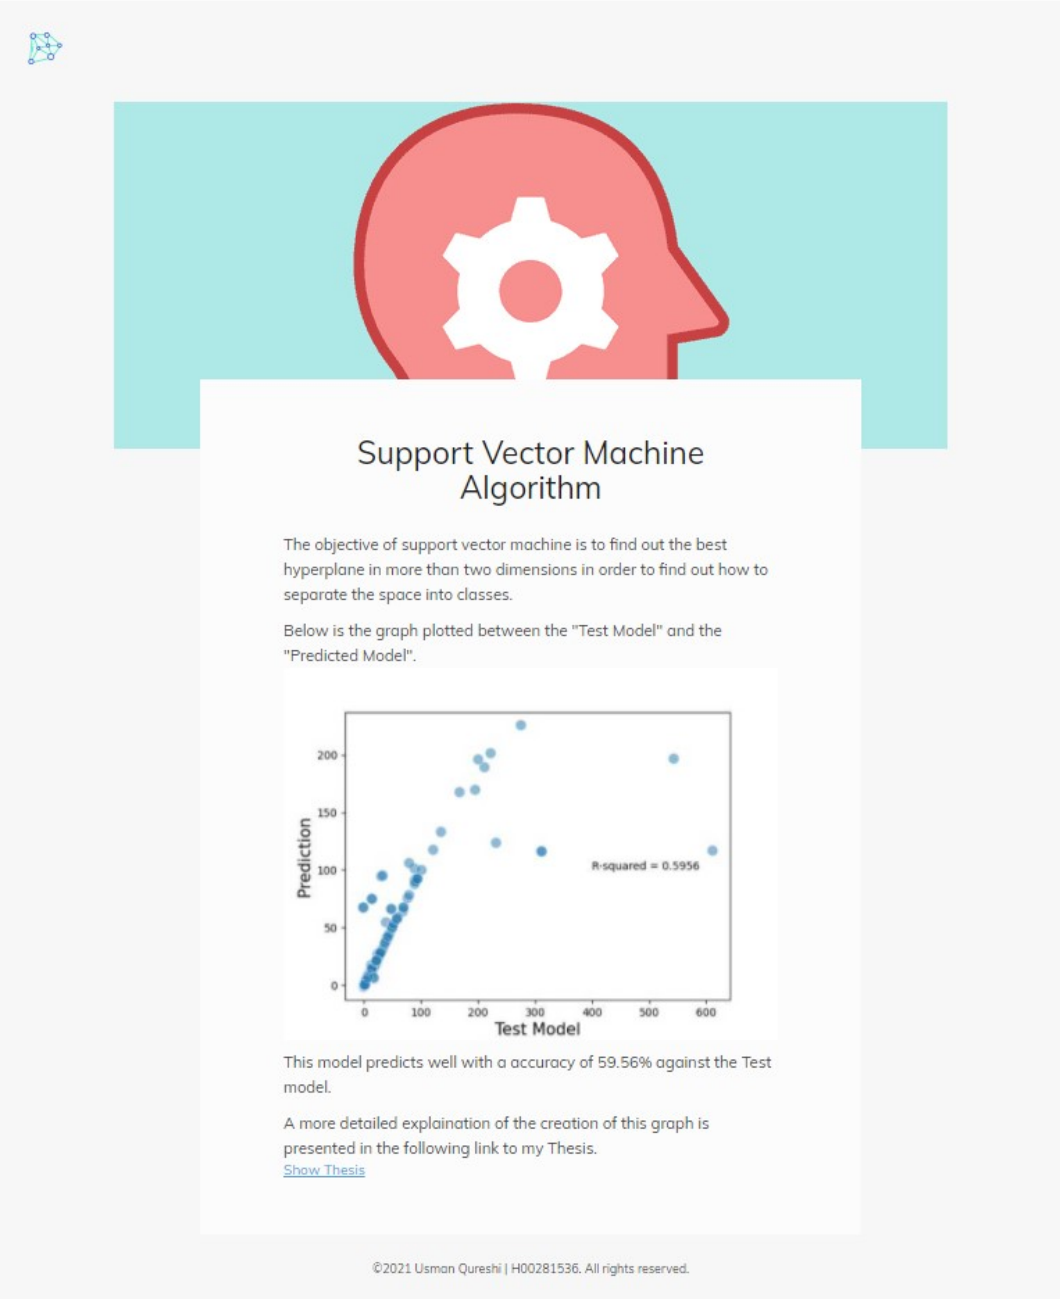
FIGURE 17: Linear Regression Page

Support Vector Machine and Decision Tree information are similarly accessed and the pages of each are shown in Figure 18 and Figure 19 respectively.



Support Vector Machine Algorithm

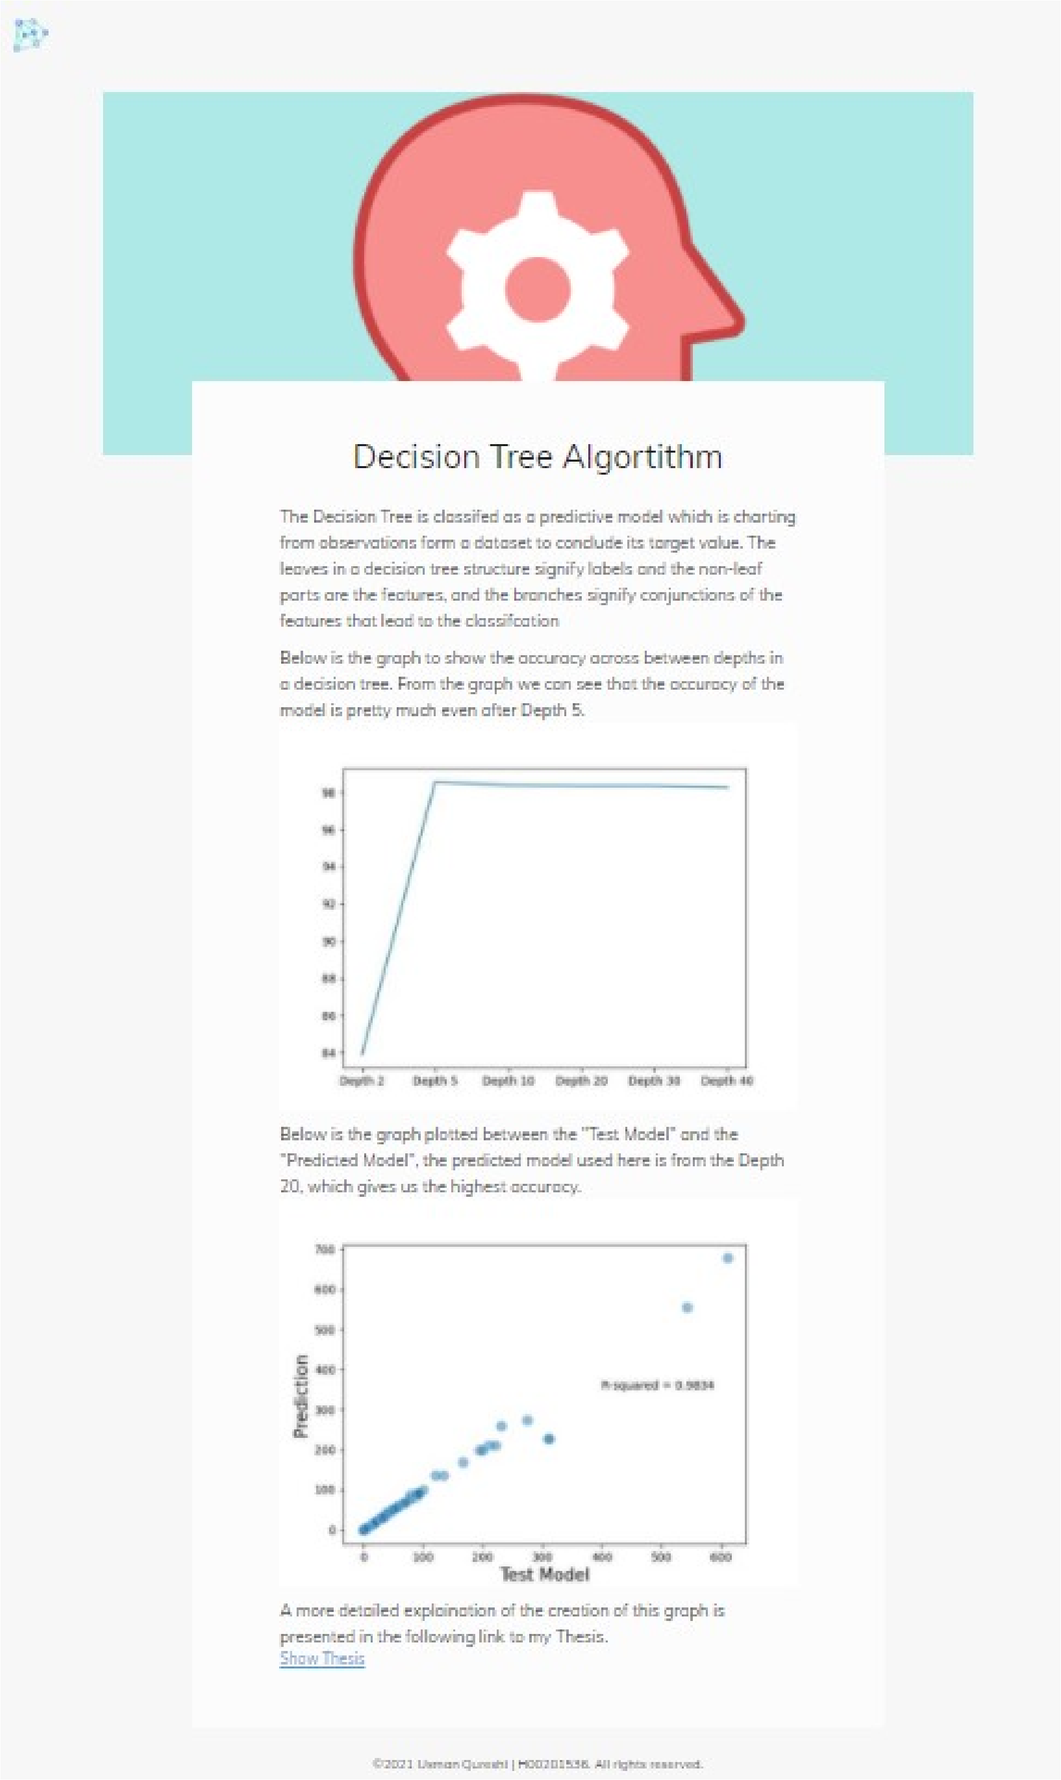
The objective of support vector machine is to find out the best hyperplane in more than two dimensions in order to find out how to separate the space into classes.

Below is the graph plotted between the "Test Model" and the "Predicted Model".

This model predicts well with a accuracy of 59.56% against the Test model.

A more detailed explaination of the creation of this graph is presented in the following link to my Thesis.
Show Thesis

Figure 18: Support Vector Machine Page



Decision Tree Algortithm

The Decision Tree is classifed as a predictive model which is charting from observations form a dataset to conclude its target value. The leaves in a decision tree structure signify labels and the non-leaf parts are the features, and the branches signify conjunctions of the features that lead to the classifcation

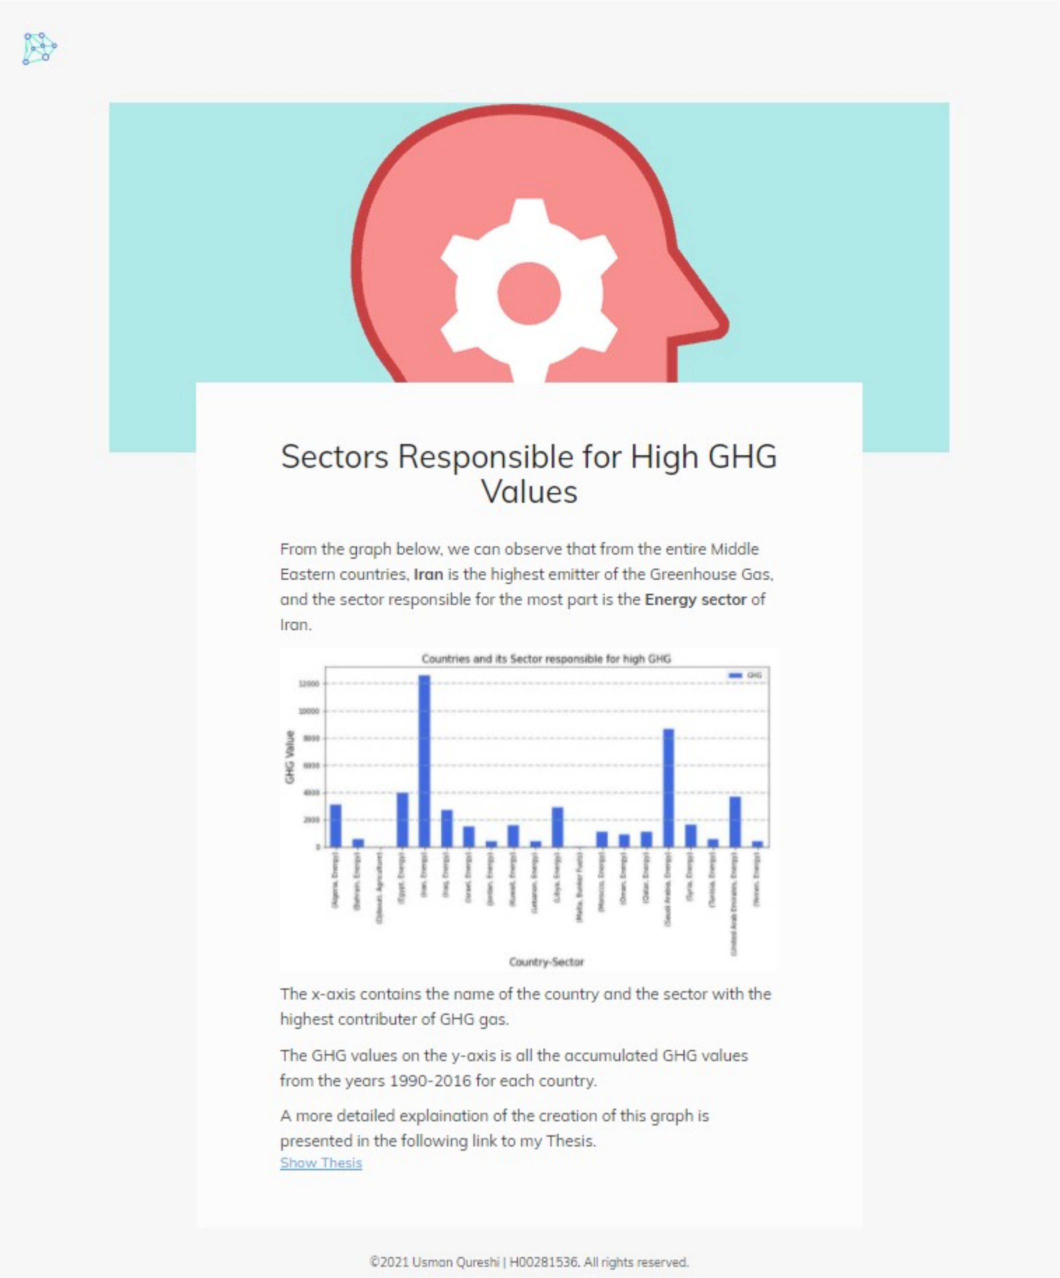
Below is the graph to show the accuracy across between depths in a decision tree. From the graph we can see that the accuracy of the model is pretty much even after Depth 5.

Below is the graph plotted between the "Test Model" and the "Predicted Model", the predicted model used here is from the Depth 20, which gives us the highest accuracy.

A more detailed explaination of the creation of this graph is presented in the following link to my Thesis.
Show Thesis

Figure 19: Decision Tree Page

Page about the details about the Countries and their sectors which are responsible for high emissions in their respective countries is shown in Figure 20



Sectors Responsible for High GHG Values

From the graph below, we can observe that from the entire Middle Eastern countries, **Iran** is the highest emitter of the Greenhouse Gas, and the sector responsible for the most part is the **Energy sector** of Iran.

The x-axis contains the name of the country and the sector with the highest contributer of GHG gas.

The GHG values on the y-axis is all the accumulated GHG values from the years 1990-2016 for each country.

A more detailed explaination of the creation of this graph is presented in the following link to my Thesis.

Chapter 6

Results and Evaluation

In this section, we are going to discuss the results of the Machine Learning algorithms implemented on the Middle Eastern Countries dataset, and, also the findings of the countries which are responsible for high emissions. This section also covers the requirements evaluation.

6.1 Results

6.1.1 Machine Learning Algorithms Result

After creating the models for the three algorithms namely Linear Regression, Support Vector Machine and Decision Trees which are briefly discussed in sections 5.3.1, 5.3.2 and 5.3.3 respectively. The understanding of the results for each algorithm is shown in the following table 6.1, table 6.2, and the table 6.3.

Linear Regression	
Evaluations	**Accuracy**
Mean Square Error (MSE)	3.49
Mean Absolute Error (MAE)	0.7965
Variance Score	0.9994
R^2	99.94%

Table 6.1: Linear Regression Table

Support Vector Machine	
Evaluations	**Accuracy**
Mean Square Error (MSE)	2108.67
Mean Absolute Error (MAE)	8.9998
Variance Score	0.5991
R^2	59.96%

Table 6.2: Support Vector Machine Table

Decision Tree	
Evaluations	**Accuracy**
Mean Square Error (MSE)	84.36
Mean Absolute Error (MAE)	1.6486
Variance Score	0.9838
R^2	98.38%

Table 6.3: Decision Tree Table

From the table we can see that the algorithm **Linear Regression** Performs the best in comparison to the other algorithms with the accuracy of **99.94 %**, and the least performing accuracy was seen in **Support Vector Machine** with a accuracy of **59.96 %**.

6.1.2 Countries and its Sector Findings

Figure 13 shows us that the Country **Iran** is responsible for the highest emission in the Middle East. And the sector contributing to the most of the emission in Iran is the **Energy sector**,followed by **Saudi Arabia** and its sector being **Energy**. The country with the least amount of emission is **Djibouti**.

6.1.3 Requirements Evaluation

This section covers the evaluation of the requirements i,e., Functional and Non-Functional, after the completion of the development. The evaluation is based on which requirements are completed, and which are not.

6.1.3.1 Functional Requirements Evaluation

FR:1 THE DATA SHOULD BE PREPROCESSED

- Priority: Must
- Condition: Completed
- The data is preprocessed for the creation of model

FR:2 THE SYSTEM SHOULD BE ABLE TO ANALYZE THE DATASET

- Priority: Must
- Condition: Completed
- The program is able to analyze the dataset after testing it thoroughly.

FR:3 THE SYSTEM SHOULD IMPLEMENT LINEAR REGRESSION

- Priority: Must
- Condition: Completed
- The program has implemented the linear regression algorithm

FR:4 THE SYSTEM SHOULD IMPLEMENT SUPPORT VECTOR MACHINE

- Priority: Must
- Condition: Completed
- The program has implemented the support vector machine algorithm

FR:5 THE SYSTEM SHOULD IMPLEMENT DECISION TREE

- Priority: Must
- Condition: Completed
- The program has implemented the decision tree algorithm

FR:6 THE SYSTEM SHOULD GENERATE ACCURATE RESULTS FROM THE MODEL

- Priority: Must
- Condition: Completed
- The program is able to generate results from the model accurately.

FR:7 THE GUI SHOULD SHOULD BE FUNCTIONAL

- Priority: Must
- Condition: Completed
- The GUI is developed and has been tested properly.

6.1.3.2 Non-Functional Requirements Evaluation

NFR:1 THE SYSTEM SHOULD BE SCALABLE

- Priority: Should
- Condition: Completed
- The system is designed in such a way that there is scope for future work.

NFR:2 THE SYSTEM SHOULD BE ABLE TO RUN ON ANY OS

- Priority: Could
- Condition: Completed
- The system is functional on any type of operating system.

NFR:3 THE USER SHOULD BE ABLE TO READ THE PRESENTED DATA

- Priority: Must
- Condition: Completed
- The system is designed in such a way that any age group is able to read the data.

NFR:4 THE GUI SHOULD BE EASY TO USE

- Priority: Should
- Condition: Completed
- The system is designed in such a way that any age group can easily browse the site.

Chapter 7

Achievements and Future Work

7.1 Achievements

The project has successfully implemented all the Machine Learning Algorithms namely Linear Regression, Support Vector Machine and Decision tree and also, the discovery of information regarding which Country in the Middle East is responsible for high Greenhouse gas emissions. All of the aims and objectives stated in section 1.1 and section 1.2 have been successfully implemented.

To show all the results for the aims and objectives, a GUI was implemented which showed the different algorithms' graphs and its accuracy for information to the user and another section showing the countries responsible for high emissions. The algorithms showed us that the Linear Regression Algorithm showed the highest accuracy with **99.94%**, and the Country with the highest Greenhouse Gas emission was **Iran** and the Sector responsible in the country is the **Energy** sector.

7.2 Future Work

After developing the system and meeting all the requirements of aim and objectives, there still are ways in which the overall system can be developed into. Throughout the project's progress, it was kept in mind that there was space for further future growth, some of them are as follows:

- Prediction of the following years from 2016 using Linear Regression and observing the trend of either rise or fall in Greenhouse gases.
- Creating interactive graphs using d3.js or any other library.
- Use a bigger dataset to implement Neural Network algorithms.

These were possible to implement but due to time constraint it was not an option to risk increasing the time allocated to development which in turn reduces the time for writing.
